

ABSTRACT OF THE DISCLOSURE

The tilt mechanism has a pair of tubular members and a catch which is fixedly mounted in the upper member and pivotally mounted in the lower member to permit tilting of the two members relative to each other. A pin is mounted in the lower member and is biased into one of several recesses in the lower end of the catch in order to hold the sections in either an upright or a tilted position relative to each other. A coil spring is used to bias the pin into a recess of the catch. Pulling down on the pin allows the tubular members to be tilted relative to each other.

#108427 v1 - Umbrella Tilt Mechanism
